

Social Computing Homework 1
Alex Litchfield

Question 1:

The groupAOutput.txt and groupBOutput.txt files are provided. Additionally, the hw1.py file is provided, which generates the answers/files to questions 1, 3a, and 3b.

Question 2a:

Male chat participants do not speak in significantly shorter sentences than do female chat participants.

Question 2b:

Male chat participants do not use significantly more pronouns than do female chat participants

Question 3a:

The table is provided in the pt3Output.txt file

Question 3b:

The average number of pronouns used by males is 140.0. The average number of pronouns used by females is 105.875

Question 3c:

Result from online calculator:

The t-value is 0.68472. The p-value is .255383. The result is not significant at $p < .05$

Using the value of p calculated above, the alternate hypothesis H_{2b} is *not* true. Even though the answer in 3b [the averages of the pronouns used by each gender] suggests that the alternate hypothesis is true, the high value of p suggests otherwise. This is because a higher value of p signifies a larger probability that the occurrence took place simply by chance and not because of some actual correlation between the genders and their usage of pronouns.
